**(54) Title: GENETICALLY ENGINEERED MODIFICATION OF POTATO TO FORM AMYLOSE-TYPE STARCH**

Antisense constructs. Outside RB and LB as pBIN19

**(57) Abstract**

Genetically engineered modification of potato for suppressing formation of amylopectin-type starch is described. The invention describes an antisense construct for inhibiting, to a varying extent, the expression of the gene coding for formation of branching enzyme (BE gene) in potato, said antisense construct comprising a tuber-specific promoter, transcription start and the first exon of the BE gene, inserted in the antisense direction. Also cells, plants, tubers, microtubers and seeds of potato comprising said antisense construct are described. Finally, amylose-type starch, both native and derivatised, derived from the potato that is modified in a genetically engineered manner, as well as a method of suppressing amylopectin formation in potato are described.

GENETICALLY ENGINEERED MODIFICATION OF POTATO  
TO FORM AMYLOSE-TYPE STARCH

The present invention relates to genetically engineered modification of potato, resulting in the formation of an increasing amount of amylose-type starch as compared to amylopectin-type starch in the potato. The genetically engineered modification implies the insertion of a gene fragment into potato, said gene fragment comprising transcription start and a part of the gene coding for the formation of branching enzyme (BE gene) in potato, inserted in the antisense direction, together with a tuber-specific promoter.

Background of the Invention

Starch in various forms is of great import in the food and paper industry. In future, starch will also be a great potential for producing polymers which are degradable in nature, e.g. for use as packing material. Many different starch products are known which are produced by derivatisation of native starch originating from, inter alia, maize and potato. Starch from potato and maize, respectively, is competing in most market areas.

In the potato tuber, starch is the greatest part of the solid matter. About 1/4 to 1/5 of the starch in potato is amylose, while the remainder of the starch is amylopectin. These two components of the starch have different fields of application, and therefore the possibility of producing either pure amylose or pure amylopectin is most interesting. The two starch components can be produced from common starch, which requires a number of process steps and, consequently, is expensive and complicated.

It has now proved that by genetic engineering it is possible to modify potato so that the proportion between the two starch components amylose and amylopectin changes in the actual tubers. As a result, a starch quality is obtained which can compete in the areas where potato starch is normally not used today. Starch from such potato

which is modified in a genetically engineered manner has great potential as a food additive, since it has not been subjected to any chemical modification process.

### Starch Synthesis

5       The synthesis of starch and the regulation thereof are presently being studied with great interest, both on the level of basic research and for industrial application. Although much is known about the assistance of certain enzymes in the transformation of saccharose into  
10 starch, the biosynthesis of starch has not yet been elucidated. By making researches above all into maize, it has, however, been possible to elucidate part of the ways of synthesis and the enzymes participating in these reactions. The most important starch-synthesising enzymes for  
15 producing the starch granules are starch synthase and branching enzyme. In maize, three forms of starch synthase have so far been demonstrated and studied, two of which are soluble and one is insolubly associated with the starch granules. Also branching enzyme in maize consists  
20 of three forms which are probably coded by three different genes.

### Branching Enzyme in Different Plant Species

The starch granules contain a mixture of linear and branched molecules which form the starch components amylose and amylopectin. Amylopectin is produced by interaction between starch synthase and branching enzyme,  
25 alpha-1,4-glucane; alpha-1,4-glucane-6-glucosyl transferase (EC 2.4.1.18). Branching enzyme (BE) hydrolyses alpha-1,4 bonds and synthesises alpha-1,6 bonds (Mac  
30 Donald & Preiss, 1985; Preiss, 1988).

Endosperm of normal maize contains three forms of BE protein, designated BE I, BE IIa and BE IIb. The mutation amylose extender (ae) inhibits the activity of the enzyme BE IIb, which results in a reduced content of amylopectin  
35 and a corresponding increase of the amylose content. ae endosperm thus has a different proportion of amylose to

amylopectin than normal maize, viz. 65:35 instead of 25:75 (De Vries Kuranda, 1987).

Although the similarities between the three enzyme forms are great, each of them has properties in its primary structure which make them unique. The genes for each enzyme form have not been identified so far, but by isolation of cDNA clones for each BE form, each gene can in all probability be characterised.

In normal pea, two forms of branching enzyme (BE) have been identified. A mutation in r locus, which results in a creased pea, affects the activity of BE, thereby inhibiting one enzyme form. This results in a modified composition of the starch with 30% amylopectin and 70% amylose, as compared to the reversed proportion in round normal pea (Smith, 1988).

Branching enzyme (BE) in potato is a monomer protein, i.e. it is a single enzyme form. The molecular weight of potato BE varies between 79 and 103 kD, depending on the purifying process used. There are indications that potato BE should consist of several forms, but presumably several forms are degradation products from the actual protein (Vos-Scheperkeuter, 1989; Blennow & Johansson, 1990).

Peptide sequencing of three BE forms, separated by electrophoresis, has such great homology between the enzyme forms that these are assumed to have the same origin. Serological tests support this assumption, since antisera from the three enzyme forms cross-react with each other.

#### Inhibition of Branching Enzyme

By inhibiting one of the forms of branching enzyme in maize and pea, the composition of the starch changes so that the content of amylose increases strongly at the sacrifice of the amylopectin production.

In potato, a natural genotype with an increased content of amylose has not been found so far. However, it is possible to reduce the content of BE to a varying extent, which results in the starch in the potato tuber having

increased contents of amylose as compared to common potato.

The reduction of the formation of enzyme can be accomplished in several ways, e.g. by:

- 5 - mutagen treatment which results in a modification of the gene sequence coding for the formation of the enzyme
- incorporation of a transposon in the gene sequence coding for the enzyme
- genetically engineered modification so that the expression of the gene coding for the enzyme is modified by
- 10 so-called antisense gene inhibition.

Fig. 1 illustrates a specific suppression of normal gene expression in that a complementary antisense nucleotide is allowed to hybridise with mRNA for a target gene.

15 The antisense nucleotide thus is antisense RNA which is transcribed in vivo from a "reversed" gene sequence (Izant, 1989).

By using the antisense technique, various gene functions in plants have been inhibited. The antisense construct for chalcone synthase, polygalacturonase and phosphotricin acetyltransferase has been used to inhibit the corresponding enzyme in the plant species petunia, tomato and tobacco (Van der Krol et al, 1990; Sheehy et al, 1988; Cornelissen, 1989).

25 The object of the invention is to provide a varyingly increased amylose production in potato tuber by using antisense gene inhibition.

#### Summary of the Invention

According to the invention the function of the BE gene and, thus, the amylopectin production in potato are

30 inhibited to a varying extent by using new antisense constructs. The antisense constructs according to the invention comprise a tuber-specific promoter, transcription start and the first exon of the gene coding for formation of branching enzyme (BE gene) in potato, inserted

35 in the antisense direction.

The invention also comprises a gene coding for formation of branching enzyme in potato, the so-called BE gene.

The invention further comprises vectors including the antisense constructs according to the invention.

5 In further aspects, the invention comprises cells, plants, tubers, microtubers and seeds, whose genome contains the antisense constructs according to the invention.

10 In still further aspects, the invention comprises amylose-type starch, both native and derivatised.

Finally, the invention comprises a method of suppressing formation of amylopectin-type starch in potato, whereby the potato tubers form a varyingly increased amount of amylose-type starch.

15 The invention will now be described in more detail with reference to the accompanying figures in which

Fig. 1 illustrates the principle of the antisense gene inhibition, and

20 Fig. 2 shows antisense constructs according to the invention (according to Bevan, 1984).

Moreover, the sequence of a tuber-specific promoter is shown in SEQ ID No. 1.

#### Isolation of Genomic BE Gene in Potato

25 Based on a known peptide sequence from the BE gene in potato, two synthetic oligo nucleotides overlapping one another are produced. The oligo nucleotides (produced at the Institute for Cell Biology, Uppsala, Sweden, at the applicant's request) are used for identification of cDNA clones from a cDNA library in lambda gt 11 (produced on 30 the applicant's behalf by Clontech, USA). The cDNA clones are used for isolation of the genomic BE gene from a genomic library in EMBL 3 (produced on the applicant's behalf by Clontech, USA).

#### Antisense Constructs

35 A varying increase of the amylose content in potato tubers is desired, and therefore different types of antisense genes are constructed which more or less inhibit the

expression of the BE gene in vivo. One starts from the isolated genomic BE gene, whereby the antisense constructs comprise parts of the BE gene corresponding to sequences in the region of the promoter, transcription start and the first exon.

In order to obtain both variation of the amylose content and tissue specificity, i.e. the production of amylopectin should be reduced in the potato tuber only, different tuber-specific promoters are coupled to the antisense gene. In addition to the own BE promoter of the tuber, the following promoters are used in different combinations: 35S CaMV, patatin I (obtained from Dr M. Bevan, England) and the potato GBSS promoter.

Isolation and characterisation of the potato GBSS gene is described in the simultaneously filed patent application having the title "Genetically engineered modification of potato to form amylopectin-type starch" by the same applicant, and its nucleotide sequence is shown in SEQ ID No. 1. The GBSS promoter is included in the potato gene coding for formation of granule-bound starch synthase. This is the enzyme which mainly is responsible for the formation of amylose in potato.

The binary Ti plasmides pBI 121 and pBI 101 (supplied by Clontech, USA) are used as a basis for all gene structures (Fig. 2), which means that NPT-II and the GUS gene are selection markers. The GUS gene is the gene which codes for beta-glucuronidase.

#### Transformation

The antisense constructs are transferred to bacteria, suitably by the "freeze-thawing" method (An et al, 1988). The transfer of the recombinant bacterium to potato tissue occurs by incubation of the potato tissue with the recombinant bacterium in a suitable medium after some sort of damage has been inflicted upon the potato tissue. During the incubation, T-DNA from the bacterium enters the DNA of the host plant. After the incubation, the bacteria are killed and the potato tissue is transferred to a solid

medium for callus induction and is incubated for growth of callus.

After passing through further suitable media, sprouts are formed which are cut away from the potato tissue.

- 5 As a first check that the antisense constructs have been transferred to the potato tissue, this is analysed regarding the presence of the used marker.

- 10 Further checks for testing the expression of the antisense constructs and the transfer thereof to the potato genome are carried out by e.g. southern and northern hybridisation (Maniatis et al (1982)). The number of copies of the antisense construct which has been transferred is determined by southern hybridisation.

- 15 The testing of the expression on protein level is suitably carried out on microtubers induced in vitro on the transformed sprouts, thus permitting the testing to be performed as quickly as possible.

#### Characterisation of the Starch

- 20 The composition of the starch in microtubers is identical with that of ordinary potato tubers, and therefore the effect of the antisense constructs on the amylopectin production is examined in microtubers. The proportion of amylose to amylopectin can be determined by a spectrophotometric method (e.g. according to Hovenkamp-Hermelink et al, 1988).

#### Extraction of Amylose from Amylose Potato

- 30 Amylose is extracted from the so-called amylose potato (potato in which the formation of amylopectin has been suppressed to a varying extent by inserting the antisense constructs according to the invention) in a known manner.

#### Derivatisation of Amylose

- 35 Depending on the final use of the amylose, its physical and chemical qualities can be modified by derivatisation. By derivatisation is here meant chemical, physical and enzymatic treatment and combinations thereof (modified starches).

The chemical derivatisation, i.e. chemical modification of the amylose, can be carried out in different ways, for example by oxidation, acid hydrolysis, dextrinisation, different forms of etherification, such as cationisation, hydroxy propylation and hydroxy ethylation, different forms of esterification, for example by vinyl acetate, acetic anhydride, or by monophosphatising, diphosphatising and octenyl succination, and combinations thereof.

Physical modification of the amylose can be effected by e.g. cylinder-drying or extrusion.

In enzymatic derivatisation, degradation (reduction of the viscosity) and chemical modification of the amylose are effected by means of existing enzymatic systems.

The derivatisation is effected at different temperatures, according to the desired end product. The ordinary range of temperature which is used is 20-45°C, but temperatures up to 180°C are possible.

The invention will be described in more detail in the following Examples.

#### Example 1

Production of microtubers with inserted antisense constructs according to the invention

The antisense constructs (see Fig. 2) are transferred to *Agrobacterium tumefaciens* LBA 4404 by the "freeze-thawing" method (An et al, 1988). The transfer to potato tissue is carried out according to a modified protocol from Rocha-Sosa et al (1989).

Leaf discs from potato plants cultured in vitro are incubated in darkness on a liquid MS-medium (Murashige & Skoog; 1962) with 3% saccharose and 0.5% MES together with 100 µl of a suspension of recombinant *Agrobacterium* per 10 ml medium for two days. After these two days the bacteria are killed. The leaf discs are transferred to a solid medium for callus induction and incubated for 4-6 weeks, depending on the growth of callus. The solid medium is composed as follows:

MS + 3% saccharose

2 mg/l zeatin riboside

0.02 mg/l "NAA"

0.02 mg/l "GA<sub>3</sub>"

5 500 mg/l "Claforan"

50 mg/l kanamycin

0.25% "Gellan"

Subsequently the leaf discs are transferred to a medium having a different composition of hormones, comprising:

10

MS + 3% saccharose

5 mg/l "NAA"

0.1 mg/l "BAP"

500 mg/l "Claforan"

15 50 mg/l kanamycin

0.25% "Gellan"

The leaf discs are stored on this medium for about 4 weeks, whereupon they are transferred to a medium in which the "Claforan" concentration has been reduced to 20 250 mg/l. If required, the leaf discs are then moved to a fresh medium every 4 or 5 weeks. After the formation of sprouts, these are cut away from the leaf discs and transferred to an identical medium.

The condition that the antisense construct has been 25 transferred to the leaf discs is first checked by analysing the presence of the GUS gene. Leaf extracts from the regenerated sprouts are analysed in respect of glucuronidase activity by means of the substrates described by Jefferson et al (1987). The activity is demonstrated by 30 visual assessment.

, Further tests of the expression of the antisense constructs and the transfer thereof to the potato genome are carried out by southern and northern hybridisation according to Maniatis et al (1982). The number of copies 35 of the antisense constructs that has been transferred is determined by southern hybridisation.

When it has been established that the antisense constructs have been transferred to and expressed in the potato genome, the testing of the expression on protein level begins. The testing is carried out on microtubers which have been induced in vitro on the transformed sprouts, thereby avoiding the necessity of waiting for the development of a complete potato plant with potato tubers.

Stem pieces of the potato sprouts are cut off at the nodes and placed on a modified MS medium. There they form microtubers after 2-3 weeks in incubation in darkness at 19°C (Bourque et al, 1987). The medium is composed as follows:

MS + 6% saccharose

2.5 mg/l kinetin

2.5 mg/l "Gellan"

The effect of the antisense constructs on the function of the BE gene in respect of the activity of the BE protein is analysed by means of electrophoresis on polyacrylamide gel (Hovenkamp-Hermelink et al, 1987). Starch is extracted from the microtubers and analysed regarding the presence of the BE protein.

The composition of the starch, i.e. the proportion of amylose to amylopectin, is determined by a spectrophotometric method according to Hovenkamp-Hermelink et al (1988), the content of each starch component being determined on the basis of a standard graph.

#### Example 2

Extraction of amylose from amylose potato.

Potato whose main starch component is amylose, below called amylose potato, modified in a genetically engineered manner according to the invention, is grated, thereby releasing the starch from the cell walls.

The cell walls (fibres) are separated from fruit juice and starch in centrifugal screens (centrisiler). The fruit juice is separated from the starch in two steps, viz. first in hydrocyclones and subsequently in specially designed band-type vacuum filters.

Then a finishing refining is carried out in hydro-cyclones in which the remainder of the fruit juice and fibres are separated.

The product is dried in two steps, first by predrying  
5 on a vacuum filter and subsequently by final drying in a hot-air current.

### Example 3

#### Chemical derivatisation of amylose

Amylose is sludged in water to a concentration of  
10 20-50%. The pH is adjusted to 10.0-12.0 and a quaternary ammonium compound is added in such a quantity that the end product obtains a degree of substitution of 0.004-0.2. The reaction temperature is set at 20-45°C. When the reaction  
15 is completed, the pH is adjusted to 4-8, whereupon the product is washed and dried. In this manner the cationic starch derivative 2-hydroxy-3-trimethyl ammonium propyl  
ether is obtained.

### Example 4

#### Chemical derivatisation of amylose

20 Amylose is sludged in water to a water content of 10-25% by weight. The pH is adjusted to 10.0-12.0, and a quaternary ammonium compound is added in such a quantity that the end product obtains a degree of substitution of 0.004-0.2. The reaction temperature is set at 20-45°C.  
25 When the reaction is completed, the pH is adjusted to 4-8. The end product is 2-hydroxy-3-trimethyl ammonium propyl ether.

### Example 5

#### Chemical derivatisation of amylose

30 Amylose is sludged in water to a concentration of 20-50% by weight. The pH is adjusted to 5.0-12.0, and sodium hypochlorite is added so that the end product obtains the desired viscosity. The reaction temperature is set at 20-45°C. When the reaction is completed, the pH is  
35 adjusted to 4-8, whereupon the end product is washed and dried. In this manner, oxidised starch is obtained.

Example 6

Physical derivatisation of amylose

Amylose is sludged in water to a concentration of 20-50% by weight, whereupon the sludge is applied to a heated cylinder where it is dried to a film.

Example 7

Chemical and physical derivatisation of amylose

Amylose is treated according to the process described in one of Examples 3-5 for chemical modification and is then further treated according to Example 6 for physical derivatisation.

## CLAIMS

- 5 1. Antisense construct for inhibition, to a varying extent, of the expression of the gene coding for formation of branching enzyme (the BE gene) in potato, said antisense construct comprising a tuber-specific promoter, transcription start and the first exon of the BE gene, inserted in the antisense direction.
- 10 2. Antisense construct as claimed in claim 1, further comprising a selection marker.
3. Antisense construct as claimed in claim 1 or 2, wherein the promoter is a promoter for the gene in potato, which codes for granule-bound starch synthase (GBSS) and  
15 which essentially has the nucleotide sequence stated in SEQ ID No. 1.
4. Antisense construct as claimed in claim 1 or 2, wherein the promoter is selected among the CaMV 35S promoter and the patatin I promoter.
- 20 5. Gene coding for formation of branching enzyme in potato.
6. Vector comprising an antisense construct as claimed in one or more of claims 1-4.
7. Cell of potato plant, whose genome comprises an  
25 antisense construct as claimed in one or more of claims 1-4.
8. Potato plant whose genome comprises an antisense construct as claimed in one or more of claims 1-4.
9. Potato tubers whose genome comprises an antisense  
30 construct as claimed in one or more of claims 1-4.
10. Seeds from potato plant, whose genome comprises an antisense construct as claimed in one or more of claims 1-4.
11. Microtubers of potato, whose genome comprises an  
35 antisense construct as claimed in one or more of claims 1-4.

12. Amylose-type native starch, c h a r a c t e r -  
i s e d in that it has been obtained from potato which  
has been modified in a genetically engineered manner for  
suppressing formation of amylopectin-type starch.

5 13. Derivatized amylose-type starch, c h a r a c -  
t e r i s e d in that it is amylose-type starch extracted  
from potato which has been modified in a genetically engi-  
neered manner for suppressing formation of amylopectin-  
type starch, said amylose-type starch subsequently being  
10 derivatized in a chemical, physical and/or enzymatic  
manner.

14. Method of suppressing formation of amylopectin-  
type starch in potato, c h a r a c t e r i s e d by  
genetically engineered modification of the potato by  
15 introducing into the genome of the potato tissue an anti-  
sense construct, comprising a tuber-specific promoter,  
transcription start and the first exon of the gene coding  
for formation of branching enzyme (BE gene) in potato,  
said exon being inserted in the antisense direction.

# INTERNATIONAL SEARCH REPORT

International Application No PCT/SE 91/00891

<b>I. CLASSIFICATION OF SUBJECT MATTER</b> (If several classification symbols apply, indicate all) <sup>6</sup> According to International Patent Classification (IPC) or to both National Classification and IPC IPC5: C 12 N 15/56, 9/44, A 01 H 5/00		
<b>II. FIELDS SEARCHED</b> Minimum Documentation Searched <sup>7</sup> Classification System Classification Symbols IPC5 C 12 N; A 01 H		
Documentation Searched other than Minimum Documentation to the Extent that such Documents are Included in Fields Searched <sup>8</sup> SE,DK,FI,NO classes as above		
<b>III. DOCUMENTS CONSIDERED TO BE RELEVANT<sup>9</sup></b>		
Category <sup>*</sup>	Citation of Document <sup>11</sup> with indication, where appropriate, of the relevant passages <sup>12</sup>	Relevant to Claim No. <sup>13</sup>
A	EP, A2, 0368506 (IMPERIAL CHEMICAL INDUSTRIES PLC) 16 May 1990, see especially claim 14	1-14
A	EP, A2, 0335451 (VERENIGING VOOR CHRISTELIJK WETENSCHAPPELIJK ONDERWIJS) 4 October 1989, see the whole document	1-14
P,A	PHYTOCHEMISTRY, Vol. 30, No. 2, 1991 Andreas Blennow et al: "Isolation of a Q-enzyme with M 103000 from potato tubers", cited in the application	1-14
A	PLANT PHYSIOL., Vol. 90, 1989 Greetje H. Vos-Scheperkeuter et al: "Immunological comparison of the starch branching enzymes from potato tubers and maize kernels", see page 75 - page 84 cited in the application	1-14
<p><sup>*</sup> Special categories of cited documents: <sup>10</sup></p> <p>"A" document defining the general state of the art which is not considered to be of particular relevance</p> <p>"E" earlier document but published on or after the international filing date</p> <p>"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)</p> <p>"O" document referring to an oral disclosure, use, exhibition or other means</p> <p>"P" document published prior to the international filing date but later than the priority date claimed</p> <p>"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention</p> <p>"X" document of particular relevance, the claimed invention cannot be considered novel or cannot be considered to involve an inventive step</p> <p>"Y" document of particular relevance, the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.</p> <p>"Z" document member of the same patent family</p>		
<b>IV. CERTIFICATION</b> Date of the Actual Completion of the International Search 30th March 1992		Date of Mailing of this International Search Report 1992-04-01
